

Effectiveness of Dolutegravir + Lamivudine in Real-world Studies in People With HIV-1 With M184V/I Mutations: A Systematic Review and Meta-analysis

Madhusudan Kabra,¹ Tristan J. Barber,^{2,3} Clotilde Allavena,⁴ Anne-Geneviève Marcelin,⁵ Simona Di Giambenedetto,⁶ Juan Pasquau,⁷ Nicola Gianotti,⁸ Matthew Turner,⁹ Cale Harrison,⁹ Tammy Wynne,⁹ Gustavo Verdier,¹⁰ Chris Parry,¹ Bryn Jones,¹ Chinyere Okoli,¹ Julie Priest,¹¹ Emilio Letang¹²

- Using real-world data from people with HIV-1 (PWH), a systematic literature review and a meta-analysis were performed to investigate the impact of historical or archived M184V/I on the effectiveness of dolutegravir + lamivudine (DTG + 3TC) in real-world switch populations; a sensitivity analysis was performed using data from randomized controlled trials (RCTs) identified via a targeted literature review
- Virologic failure (VF) incidence was low, and no treatment-emergent INSTI resistance mutations were reported in populations with M184V/I that switched to DTG + 3TC, providing reassurance that M184V/I may have a limited impact on the efficacy of DTG + 3TC in PWH considering treatment change when drug resistance-associated mutations (RAMs) are unknown or inadvertently missed

Introduction

- M184V/I is the most common RAM selected by 3TC¹
- Clinical development phase 3 RCTs excluded participants with known or suspected RAMs
- The presence of archived M184V/I mutations in phase 3 trials evaluating switch to DTG/3TC (TANGO, n=4; SALSA, n=5)^{2,3} did not impact virologic efficacy
- Absence of historical resistance results or availability of prior genotype (pooled TANGO/SALSA analysis, n=294) also had no impact on results⁴
- In clinical practice, prior history of resistance is not always available when considering treatment options • Real-world evidence (RWE) can help address the knowledge gap of whether switching to DTG + 3TC is safe in real-world clinical practice when full treatment history or historical genotype results are not available

Figure 1. PRISMA Flow Charts for (A) RWE Studies and (B) RCTs

- This meta-analysis describes VF at Weeks 24, 48, and 96 using real-world data from PWH receiving DTG + 3TC in a suppressed switch setting, with historical RNA- or archived proviral DNA-detected M184V/I mutation
- A sensitivity analysis was performed using RCT data

Methods

- A systematic literature review was performed following Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines (Figure 1A)
- Embase[®], Ovid MEDLINE[®], MEDLINE[®] In-Process, and Cochrane library (January 2013-March 2022) and relevant conference archives (2016-2021) were searched for real-world studies reporting virologic outcomes for PWH receiving DTG + 3TC
- A targeted literature review was performed to identify RCTs assessing M184V/I impact on DTG + 3TC efficacy (Figure 1B)
- Studies were screened for suppressed switch populations reporting M184V/I mutations before DTG + 3TC initiation
- For the primary objective, common- and random-effects model analyses were conducted using RWE studies
- Random-effects models provide estimates that are more generalizable to the overall population of interest
- Common-effects (or fixed-effects) models assume that the included studies are the population of interest and are more informative when zero VF events are observed
- For the secondary objective, sensitivity analyses were performed using RCT data
- In both RWE and RCT data sets, base analyses were performed using studies with identical VF definitions; sensitivity analyses were performed using all studies regardless of VF definition to maximize sample size

Results

VF Outcomes in RWE Studies and RCTs

- Of 3492 publications and 198 conference abstracts identified via systematic literature review, 5 real-world studies met all search criteria and were analyzed (Table)
- The targeted literature review also identified 5 relevant RCTs
- Proportions of PWH with historical M184V/I estimated to have VF at Weeks 24, 48, and 96 were low in

Figure 2. Meta-analysis Estimates of Proportions of VF at Weeks 24, 48, and 96 in PWH With Reported M184V/I Receiving DTG + 3TC From (A) Systematic Literature Review–Identified RWE Studies and (B) Targeted Literature Review–Identified RCTs, Inclusive of All VF Definitions

real-world and RCT analyses based on reported VF outcomes at each time point

- Real-world: 3/186 (1.61%), 7/237 (2.95%), and 7/186 (3.76%), respectively
- RCT: 0/38 (0%), 2/93 (2.15%), and 0/34 (0%), respectively
- No treatment-emergent resistance mutations were reported

• Including all studies regardless of VF definition increased sample sizes without significantly impacting estimates

NR, not reported. aCohort reference reporting the proportion with VF for individuals with M184V/I was used for analysis (n=45 individuals with M184V/I).8 bAssumption: n=60 PWH with M184V/I were reported out of N=220 total PWH with available pre-switch genotype resistance data across 2 groups but not reported for DTG + 3TC specifically. Table n with M184V/I was calculated according to the proportion of PWH in the DTG + 3TC (n=174) vs other group (n=46). Assumption: Week 24 was not reported, but reports described no VF to Week 48. ^dAssumption: VFs and discontinuations were not directly reported; study reported n (%) with VL <40 c/mL and TND, and here VF is assumed to be VL ≥40 c/mL.

VF Estimates

- Random-effects models are associated with greater uncertainty vs common-effects models but can be used to estimate results for the wider population of interest based on the sample of studies used in the analysis • Common-effects (or fixed-effects) models assume that the included studies are the population of interest and can be more appropriate and informative when zero VF events are observed
- RWE common-effects models estimated the proportions (95% CI) of individuals with VF were 0.01 (0.00-0.03) at Week 24, 0.03 (0.01-0.06) at Week 48, and 0.04 (0.02-0.08) at Week 96; random-effects estimates are in Figure 2A
- RCT common-effects models estimated the proportions (95% CI) of individuals with VF were 0.01 (0.00-0.05) at Week 48 and 0.00 (0.00-0.03) at Week 96; random-effects estimates for these time points are in Figure 2B
- Common-effects models better represented Week 24 data consisting of zero observed events (Figure 2B); random-effects models estimated Week 24 proportions (95% CI) were 0.00 (0.00-0.00)

Proportions were log-transformed, or arcsine-transformed if any studies reported zero events.

Conclusions

• Overall, pre-switch M184V/I prevalence was low in PWH in RWE studies

- Real-world studies of PWH with historical or archived M184V/I receiving DTG + 3TC identified low incidence of VF through 96 weeks and no reported cases of INSTI treatment-emergent mutations; these findings were consistent with results from RCTs
- Genotypic data at the time of VF were unavailable and the occurrence of resistance mutations to 3TC or DTG at failure could not be described
- This meta-analysis provides reassuring data on outcomes with DTG + 3TC in PWH with incomplete history or in cases where M184V/I was inadvertently missed
